Steps to perform Manual Testing Operation in JMeter.

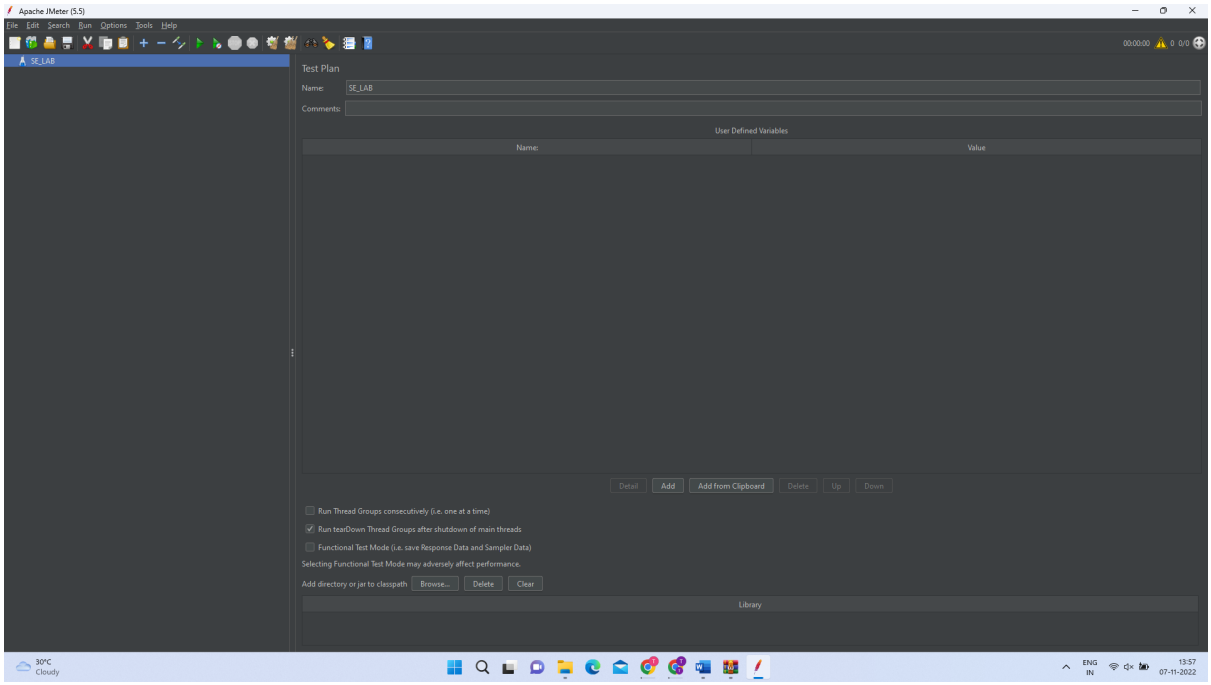

Step 1: Install the JMeter in your local system.

Step 2: Open the ApacheJMeter.jar file

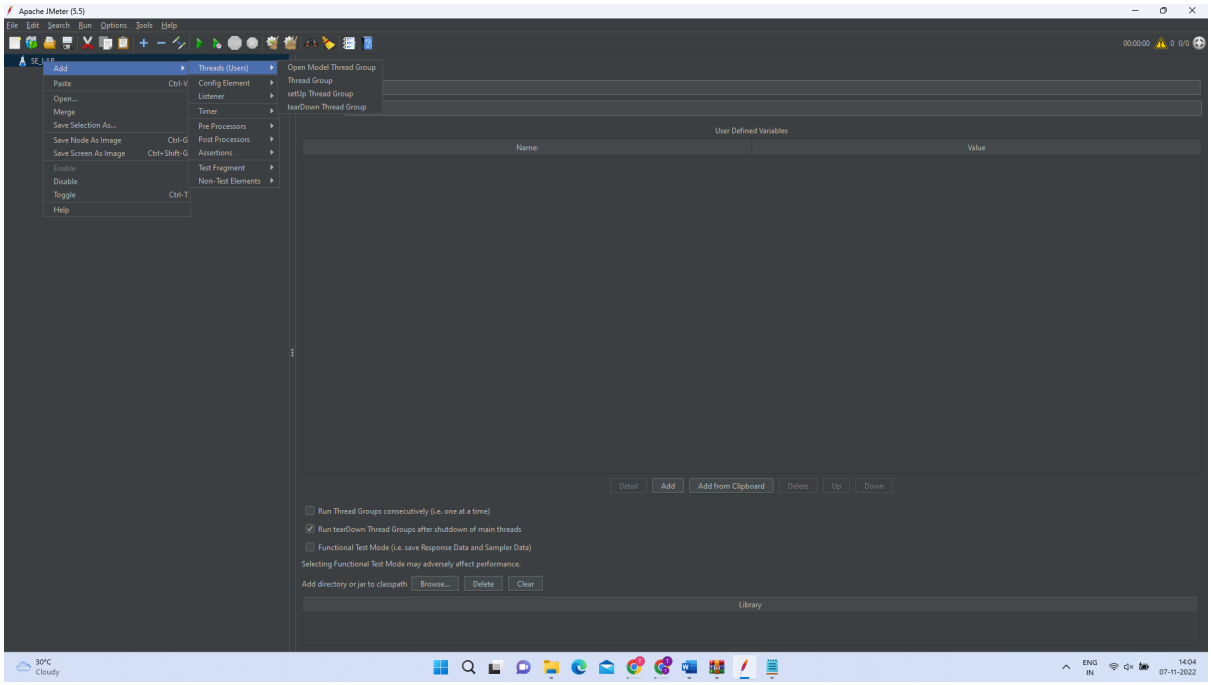

Step 3: As it contains Thread Group, Samplers, Listeners and Configurations.

Step 4: Now you can add Threads, Configurations, Listeners and Samplers of your choice.

- Thread group is the basic element of the Jmeter Test plan. As said in the name Thread group is a group of threads that are executing the same scenario. This is considered the beginning point of a test plan. Thread group holds other test elements like controllers, samplers, config elements also the listeners.
- Samplers tell JMeter to send requests to a server and wait for a response. They are processed in the order they appear in the tree.
- Listeners provide access to the information JMeter gathers about the test cases while JMeter runs. The Graph Results listener plots the response times on a graph. The "View Results Tree" Listener shows details of sampler requests and responses, and can display basic HTML and XML representations of the response. Other listeners provide summary or aggregation information.
- Configuration Elements allow you to create defaults and variables to be used by Samplers. They are used to add or modify requests made by Samplers. They are executed at the start of the scope of which they are part, before any Samplers that are located in the same scope.

For more processors and operators refer this

Process to start the testing operation for your own subject project so as to decide on all parameters of your choice.

Suppose if you have deployed your project on any domain, you can use the HTTP request sampler to check that the connection has been properly established.

Else if you are using any Machine Learning model then you can use Streamlit and Jmeter for performing required Testing Operation where you can take the idea from this reference: https://www.youtube.com/watch?v=2MEY5gw97_U

Perform minimal number of testing operations in order to refrain yourself from any confusion and model or application redundancy. As it is freely available and human interactive you can solve a large number of testing operations and solutions at a minimal amount of time.
